Abstract

A triangular array of independent non-identically distributed random variables is considered. The distribution functions of centered and rescaled sums of the random variables are estimated by resampling from the lists of their observed values. The estimators of distributions are called consistent (in probability) if they are weakly approaching the estimated distributions in probability, as the number of observations increases to infinity. Under some additional assumptions this type of consistency implies convergence in several metrics, e.g. in the uniform metric. A necessary and sufficient condition for consistency is given. In addition a new formulation of the Central Limit Theorem for triangular arrays, related to the notion of weakly approaching distribution functions, is stated. These results can be applied to justify the possibility of using resampling (bootstrap) techniques in many statistical applications, e.g. to justify the method of resampling from the list of weighted residuals in the case of a linear heteroscedastic regression.

Key words: triangular array, non-identically distributed random variables, central limit theorem, resampling, consistent estimation of distribution functions

1 Introduction

The following statistical problem will be considered. There is a process of collecting statistical data \( \{x_{1n}, \ldots, x_{nn}\} \), \( n \to \infty \). The components \( \{x_{hn}\} \) are values of independent non-identically distributed random variables (r.v.s). One can consider \( \frac{1}{\rho_n} \sum_{h=1}^{n} (x_{hn} - u_{hn}) \) as the observed value of the sum of the r.v.s, centered by \( \{u_{hn}\} \) and rescaled by \( \rho_n \). In many applications, it is useful to find estimators of the distributions of the centered and rescaled sums of r.v.s. The estimators have to be in some sense consistent. We will say that the estimators of distributions are (weakly) consistent if they are weakly approaching in probability to the estimated distributions. This type of consistency has been used in a paper by Belyaev (1995). An exact definition of this notion is given in the Appendix. Here, we say only that the notion of weakly approaching distributions is a convenient extension of weak convergence and that under some additional assumptions it implies convergence in the uniform metric and some other metrics, see Belyaev and Sjöstedt-de Luna (2000). We will find appropriate estimators by using resampling from the data \( \{x_{1n}, \ldots, x_{nn}\} \). In this paper, we restrict ourselves to the case where the centered and rescaled sums of r.v.s are weakly approaching to the family of normal distributions. Our assumptions sufficient for consistency of considered estimators, are rather general, e.g. we avoid stating direct assumptions on existence of moments of random variables.

Theorems 1, 2 and 3 are the main results of this paper. Assumptions \( A_1 \), \( A_2(\tau) \) and \( A_3(\tau) \) related to behavior of individual r.v.s, their sums, and expectations, respectively, are stated in the next section. Theorem 1 is an upgraded version of the well-known Central Limit Theorem where we use rather general assumptions \( A_1 \) and \( A_2(\tau) \), which imply that the distributions of centered and rescaled sums of r.v.s are weakly approaching the family of normal distributions. Theorem 2 states that if assumptions \( A_1 \) and \( A_2(\tau) \) hold, then \( A_3(\tau) \) is a necessary and sufficient condition that distributions of resampled, rescaled and centered sums based on the data \( \{x_{1n}, \ldots, x_{nn}\} \), are weakly approaching in probability the distributions of related, centered and rescaled sums of r.v.s. In short, Theorem 2 says that resampling is valid for consistent estimation of the distribution of interest if and only if the assumption \( A_3(\tau) \) holds. Theorem 3 contains rather general assumptions which are sufficient for the usage of resampling in linear heteroscedastic regression.

The validity of resampling in the case of independent and identically distributed (i.i.d.) r.v.s has been carefully and exhaustively considered in a series of papers and books, for references see Hall (1992). In the case of i.i.d.
r.v.s the necessary condition for consistency of resampling has been obtained in Giné and Zinn (1989). The case of i.i.d. r.v.s with the infinite variance is quite different. It has been considered in the pioneer paper Athreya (1987). In the case of non-identically distributed independent r.v.s the situation is more complex. The most interesting results have been obtained in a paper by Mammen (1992) where the necessary and sufficient condition for validity of resampling has been found, in the case of a triangular array of independent real-valued r.v.s, and where the uniform distance between distributions has been used. The proofs in Mammen (1992) are rather long and many special results are used there. In our paper, quite different methods are used in the proofs related to the necessary and sufficient assumption $A_3(\tau)$, which is close to that obtained by Mammen (1992). Instead of distributions convergent in the uniform metric we consider distributions weakly approaching in probability. Convergence in the uniform metric is obtained as a special case in Corollary 1 and Corollary 2. The methods suggested in this paper can easily be extended to the case of vector-valued r.v.s. One can encounter similar problems related to resampling if statistical data contain realisations of random processes, see e.g. Belyaev and Seleznjev (2000). The methods are rather simple because the notion used of weakly approaching distributions is directly connected with the pointwise convergence of the corresponding characteristic functions. Proofs of Theorems 1 and 2 are based on the analysis of characteristics functions.

The paper is organised as follows: In the next section we introduce most of the notation used and state the basic results. An application to heteroscedastic linear regression is given in Section 3. After that we present proofs of the stated results. The proofs are split into a series of lemmas. Several necessary definitions and propositions are presented in the Appendix. They are referred to the text as Definition 1, Proposition 1 etc. The notations $\overset{\text{w}}{\to}$ and $\overset{\text{w}(P)}{\to}$ are also explained in the Appendix.

2 Basic results

We use the following notation: Capital letters denote r.v.s, $E$ and $P$ are symbols of expectation and probability, respectively, $\xrightarrow{P}$ means convergence in probability, $\mathcal{L}(X)$ is the distribution law (d.l.) of an r.v. $X$, $\mathbb{I}(A)$ is the indicator of an event $A$. By $\{\rho_n\}_{n \geq 1}$ we denote a sequence of positive non-random values which will be used to norm (rescale) r.v.s. Let $X = \{X_{hn} : \{h, n\} \in \mathcal{I}\}$ be a triangular array of real r.v.s $\{X_{hn}\}$ which are independent for each $n = 2, 3, \ldots$, $\mathcal{I} = \{\{h, n\} : n = 1, 2, \ldots, h = 1, 2, \ldots, n\}$, $X_n = \{X_{1n}, \ldots, X_{nn}\}$. 

3
The r.v.s $X_{hn}$, $h = 1, \ldots, n$, can be non-identically distributed. We consider the normed and shifted or centered r.v.s $Y_{hn} = X_{hn}/\rho_n$. Let $Y_{hn}(\tau) = Y_{hn}I(|Y_{hn}| \leq \tau)$, $\bar{Y}_{hn}(\tau) = Y_{hn} - E[Y_{hn}(\tau)]$, $Y_{hn}^\circ(\tau) = \sum_{h=1}^n Y_{hn}^\circ(\tau), Y_{hn}^\circ(\tau) = Y_{hn}(\tau) - E[Y_{hn}(\tau)]$, $\sigma_n^2(\tau) = \text{Var}[Y_{hn}^\circ(\tau)] = \sum_{h=1}^n \text{E}[(Y_{hn}^\circ(\tau))^2]$. We will use notation $Y_{hn}^\circ = Y_{hn} - E[Y_{hn}]$, $Y_n^\circ = \sum_{h=1}^n Y_{hn}^\circ$ and $\sigma_n^2 = \sum_{h=1}^n E[(Y_{hn}^\circ)^2]$ if $\text{E}[Y_{hn}^2] < \infty$, $\{h, n\} \in \mathcal{T}$. We will also consider two lists of r.v.s

$$Y_n^\circ = \{Y_{1n} - \bar{Y}_n, \ldots, Y_{nn} - \bar{Y}_n\},$$

and

$$Y_n^\circ(\tau) = \{Y_{1n}(\tau) - \bar{Y}_n(\tau), \ldots, Y_{nn}(\tau) - \bar{Y}_n(\tau)\},$$

where

$$Y_n = \sum_{h=1}^n Y_{hn}, \quad \bar{Y}_n = Y_n/n, \quad Y_n(\tau) = \sum_{h=1}^n Y_{hn}(\tau), \quad \bar{Y}_n(\tau) = Y_n(\tau)/n, \quad \tau > 0.$$

Let $J_n^* = \{J_{1n}^*, \ldots, J_{nn}^*\}$, be n i.i.d. r.v.s uniformly distributed on $\{1, 2, \ldots, n\}$, i.e. $P(J_{hn}^* = h) = 1/n$, $h = 1, \ldots, n$. We use the mark "*" to show that r.v.s, probabilities and expectations are related to $J_n^*$. Values of r.v.s $J_{hn}^*$ can be obtained by simulation. Resampling copies of lists $Y_n^\circ$ and $Y_n^\circ(\tau)$, obtained via simulation of the r.v.s $J_n^*$, will be denoted as follows

$$Y_n^\circ = \{Y_{1n}^\circ, \ldots, Y_{nn}^\circ\}, \quad Y_n^\circ(\tau) = \{Y_{1n}^\circ(\tau), \ldots, Y_{nn}^\circ(\tau)\},$$

where $Y_{hn}^\circ = Y_{hn} - \bar{Y}_n, Y_{hn}^* = Y_{hn}^\circ, Y_{hn}^\circ(\tau) = Y_{hn}^\circ(\tau) - \bar{Y}_n(\tau)$, $Y_{hn}^*(\tau) = Y_{hn}^\circ(\tau)$. Let $N_{hn}^* = \sum_{i=1}^n I(J_{hn}^* = h)$. Then, we can write the sums of components in $Y_n^\circ$ and $Y_n^\circ(\tau)$ as follows

$$Y_n^\circ = \sum_{h=1}^n (N_{hn}^* - 1)Y_{hn}, \quad Y_n^\circ(\tau) = \sum_{h=1}^n (N_{hn}^* - 1)Y_{hn}(\tau). \quad (1)$$

We introduce the following assumptions:

There exists a sequence $\{\rho_n\}_{n \geq 1}$, where every $\rho_n > 0$ and a $\tau > 0$ such that

$A_1$ : $\max_{1 \leq h \leq n} |Y_{hn}| \rightarrow 0$, $n \rightarrow \infty$;

$A_2(\tau)$ : the sequence of d.l.s $\{\mathcal{L}(Y_n^\circ(\tau))\}_{n \geq 1}$ is tight;

$A_3(\tau)$ : $\sum_{h=1}^n (E[Y_{hn}(\tau)])^2 \rightarrow 0$, $n \rightarrow \infty$. 

4
$\mathbf{A}_1$ holds if and only if for every $\varepsilon > 0$

$$\sum_{h=1}^{n} P[|Y_{hn}| > \varepsilon] \to 0, \quad n \to \infty.$$  

**Theorem 1.** (The Central Limit Theorem (CLT) for triangular array) Suppose that $\mathbf{A}_1$ holds. Then

$$\mathcal{L}(Y_n^\circ(\tau)) \xrightarrow{w_a} \mathcal{N}_1(0, \sigma_n^2), \quad n \to \infty,$$  

where $\{\sigma_n^2\}_{n \geq 1}$ is a sequence of positive numbers, $\sigma_n^2 = \sup_n \sigma_n^2 < \infty$, if and only if $\mathbf{A}_2(\tau)$ holds.

Theorem 1 says that if $\mathbf{A}_1$ holds, then the d.l.s of the sums $Y_n^\circ(\tau)$ are weakly approaching (see Definition 3) the family of normal d.l.s $\mathcal{N}_1(0, \sigma_n^2)$.

**Corollary 1.** If $\mathbf{A}_1$ and $\mathbf{A}_2(\tau)$ hold, then $\mathbf{A}_3(\tau)$ holds, if $\sum h=1^{n} (E[Y_{hn}(\tau_0)])^2 \to 0, n \to \infty$, then $\mathbf{A}_3(\tau)$ holds for any $\tau > 0$.

**Remark.** We will prove Theorem 1 and Theorem 2 with $\sigma_n^2 = \sigma_n^2(\tau)$. It will be shown that $\sigma_n^2(\tau)$ does not essentially depend on $\tau$, as $n \to \infty$, if $\mathbf{A}_1$ holds. If both $\mathbf{A}_2(\tau_1)$ and $\mathbf{A}_2(\tau_2)$ hold, $0 < \tau_1 < \tau_2 < \infty$, then $\mathcal{L}(Y_n^\circ(\tau_1)) \xrightarrow{w_a} \mathcal{L}(Y_n^\circ(\tau_2)), n \to \infty$. If $\mathbf{A}_1$ holds and for a $\tau_0 > 0$, $\sum h=1^{n} (E[Y_{hn}(\tau_0)])^2 \to 0, n \to \infty$, then $\mathbf{A}_3(\tau)$ holds for any $\tau > 0$.

Let $F_n(x) = P[Y_n^\circ(\tau) \leq x]$ and $F_n^*(x \mid X_n) = P[Y_n^\circ \leq x \mid X_n]$ be the distribution functions (d.f.s) of the r.v.s $Y_n^\circ(\tau)$, and the conditional d.f.s of $Y_n^\circ$ given $X_n$, respectively, and $\Phi(x) = \frac{1}{\sqrt{2\pi}}e^{-x^2/2}$.

**Corollary 1.** If $\mathbf{A}_1$ and $\mathbf{A}_2(\tau)$ hold and $\lim_{n \to \infty} \sigma_n^2 > 0$, then

$$\sup_x \left| F_n(x) - \Phi\left(\frac{x}{\sigma_n^2}\right)\right| \to 0, \quad n \to \infty.$$
Corollary 2. If $A_1$, $A_2(\tau)$ and $A_3(\tau)$ hold and $\lim_{n \to \infty} \sigma_n^2 > 0$, then

$$\sup_x \left| F_n^*(x \mid X_n) - \Phi \left( \frac{x}{\sigma_n} \right) \right| \overset{P}{\to} 0, \quad n \to \infty,$$

and correspondingly

$$\sup_x \left| F_n^*(x \mid X_n) - F_n(x) \right| \overset{P}{\to} 0, \quad n \to \infty.$$

The case, where all r.v.s have the finite second moments is interesting in many applications.

Corollary 3. Suppose that all second order moments $E[Y_n^2] < \infty$,

$$\sup_n \sum_{h=1}^n E[Y_n^2] = C_2 < \infty, \quad \{h_n \} \in \mathcal{T}, \quad \sum_{h=1}^n (E[Y_n])^2 \to 0, \quad n \to \infty,$$

and for every $\tau > 0$

$$\sum_{h=1}^n E[(Y_n)^2I(\mid Y_n \mid > \tau)] \to 0, \quad n \to \infty. \quad (4)$$

Then

$$\mathcal{L}(Y_n^\circ) \overset{w}{\to} \mathcal{N}_1(0, \sigma_n^2), \quad n \to \infty, \quad (5)$$

and

$$\mathcal{L}(Y_n^\circ | X_n) \overset{w(P)}{\to} \mathcal{L}(Y_n^\circ), \quad n \to \infty. \quad (6)$$

Here, the Lindeberg assumption (4) is used in order to have $\sigma_n^2$ in (5), instead of a $\sigma^2_n$ as it stated in Theorem 1. In the general case, $\sigma_n^2$ can essentially differ from $\sigma_n^2$ because, then we do not assume that the second moments are finite.

3 Application to heteroscedastic linear regression

Suppose that statistical data are the list of pairs $\{(Y_1, \{\tilde{x}_{11}, ... , \tilde{x}_{1r}\}), ..., (Y_n, \{\tilde{x}_{1n}, ..., \tilde{x}_{rn}\})\}$ with components satisfying the following relations of a linear heteroscedastic regression:

$$Y_h = \sum_{s=1}^r \tilde{x}_{sh}\beta_{s0} + W_h, \quad h = 1, ..., n, \quad (7)$$

where errors $\{W_h\}$ are independent r.v.s, $\{\tilde{x}_{sh}\}$ are explanatory variables (regressors), $\{\beta_{s0}\}$ are components of a parameter, and $\{Y_h\}$ are responses.
The errors can be non-identically distributed. We can rewrite (7) by using vector-matrix form
\[
\mathbf{Y}_n = \mathbf{X}_n \mathbf{\beta}_0 + \mathbf{W}_n,
\]
where \(\mathbf{Y}_n = \{Y_1, ..., Y_n\}^T\), \(\mathbf{X}_n = [x_{hs}]\), \(x_{hs} = \tilde{x}_{sh}\), \(\mathbf{\beta}_0 = [\beta_1, ..., \beta_0]^T\), \(\mathbf{W}_n = \{W_1, ..., W_n\}^T\), “\(\tilde{\text{tr}}\)” denotes transposition. The columns of the matrix \(\mathbf{X}_n\) can be considered as column-vectors \(\mathbf{x}_h = \{x_{1h}, ..., x_{rh}\}^T\). Let \(\mathbf{X}_n\) be the Moore-Penrose inverse matrix of \(\mathbf{X}_n^T \mathbf{X}_n\) and \(\mathbf{tr}(\mathbf{X}_n^T \mathbf{X}_n)^+\) be its trace. If \(\text{rank}(\mathbf{X}_n^T \mathbf{X}_n) = r\), then \(\mathbf{M}(\mathbf{X}_n^T) \subset \mathbb{R}^r\) be the linear space generated by vectors \(\mathbf{x}_1, ..., \mathbf{x}_n\), and \(\| \mathbf{a} \|^2 = \mathbf{a}^T \mathbf{a}\), \(\mathbf{a} \in \mathbb{R}^r\).

Suppose that \(\mathbf{c}^T \mathbf{\beta}_0\) is the parameter of interest and \(\mathbf{c} \in \mathbb{M}(\tilde{\mathbf{X}}_n^T)\). Note, that
\[
| \mathbf{a}_1^T(\tilde{\mathbf{X}}_n^T \mathbf{X}_n) + \mathbf{a}_2 | \leq \| \mathbf{a}_1 \| \| \mathbf{a}_2 \| \mathbf{tr}(\mathbf{X}_n^T \mathbf{X}_n)^+, \quad \mathbf{a}_1, \mathbf{a}_2 \in \mathbb{R}^r. \tag{8}
\]
We introduce the following assumptions:

\(\textbf{HR}_1\) : All values of explanatory variables are uniformly bounded, \(x_+ = \sup_{s,h} |\tilde{x}_{sh}| < \infty\), and for every \(\varepsilon > 0\) and a given \(\mathbf{c} \in \mathbb{M}(\tilde{\mathbf{X}}_n^T)\) it holds:
\[
(i) \quad t(\mathbf{c}, \tilde{\mathbf{X}}_n) = \frac{\mathbf{tr}(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+}{\sqrt{\mathbf{c}^T(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+ \mathbf{c}}} \to 0, \quad n \to \infty,
\]
\[
(ii) \quad \sum_{h=1}^n \mathbb{E} \left[ t^2(\mathbf{c}, \tilde{\mathbf{X}}_n) W_h^2 I(t(\mathbf{c}, \tilde{\mathbf{X}}_n) \mid W_h > \varepsilon) \right] \to 0, \quad n \to \infty;
\]

\(\textbf{HR}_2\) : There are two constants \(0 < \sigma^2_1 \leq \sigma^2_2 < \infty\) such that
\[
\sigma^2_1 \leq \sigma^2_h(\tilde{x}_h) = \mathbb{E}[W_h^2] \leq \sigma^2_2, \quad \text{and} \quad \mathbb{E}[W_h] = 0, \quad h = 1, 2, ..., n;
\]

\(\textbf{HR}_3\) : \[
\frac{n(\mathbf{tr}(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+)^3}{\mathbf{c}^T(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+ \mathbf{c}} \to 0, \quad n \to \infty.
\]

If \(\mathbf{c}^T(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+ + \mathbf{c} \to 0, \quad n \to \infty\), and \(\textbf{HR}_2\) holds, then the ordinary least-squares (OLS-estimator) \(\hat{\mathbf{c}}^T \mathbf{\beta}_0\) is unbiased and consistent. It is essential to know how accurate this estimator is. The problem has been thoroughly discussed in a paper by Wu (1986). It is interesting to estimate the d.l. of the OLS-estimator’s deviations, e.g. the d.l. \[
\mathbb{L} \left( \frac{(\hat{\mathbf{c}}^T \mathbf{\beta}_0)^n - \mathbf{c}^T \mathbf{\beta}_0}{\sqrt{\mathbf{c}^T(\tilde{\mathbf{X}}_n^T \mathbf{X}_n)^+ \mathbf{c}}} \right). \]
Here, the theory of linear regression with i.i.d
\(W_h, \ h = 1, 2, \ldots\) can not be used. However, the consistent estimation of the
d.l. can be realised by using the resampling (bootstrap) from weighted residuals.
Let \(\hat{Y}_h = \hat{x}_h^T (\tilde{X}_h^T \tilde{X}_h)^+ \tilde{X}_h^T Y_n\) be the predicted value of \(\hat{Y}_h, \ h = 1, \ldots, n\).
We can consider a resampling copy \(\{\{\hat{Y}_1^* - Y_1^*, \hat{x}_1\}, \ldots, \{\hat{Y}_n^* - Y_n^*, \hat{x}_n^*\}\}\) of the
list of residuals paired with vectors of explanatory variables
\(\{\{\hat{Y}_1 - Y_1, \hat{x}_1\}, \ldots, \{\hat{Y}_n - Y_n, \hat{x}_n\}\}\) where \(\hat{Y}_h^* = Y_{j_h}, \ h = 1, \ldots, n\), and,
\(\hat{x}_h^* = \hat{x}_{j_h}, \ h = 1, \ldots, n\). Let
\[
U_n^*(c, Y_n, \hat{x}_n^*) = \sum_{h=1}^{n} (N_{h_n}^* - 1) \frac{c^T (\tilde{X}_h^T \tilde{X}_h)^+ \hat{x}_h}{(c^T (\tilde{X}_h^T \tilde{X}_h)^+ c)^{1/2}} (Y_h - \hat{Y}_h).
\] (9)
The r.v. \(U_n^*(c, Y_n, \hat{x}_n^*)\) is the centered sum of resampled and weighted residuals.
Here, we justify usage of \(L(U_n^*(c, Y_n, \hat{x}_n^*) \mid Y_n)\) as a consistent estimator
of the d.l. of normed deviations of unbiased estimators \(c^T \beta_0\).

**Theorem 3.** Suppose that errors \(\{W_h\}_{h \geq 1}\) are independent, and that as-
sumptions HR\(_1\) and HR\(_2\) hold. Then the normed d.l.s of deviations of the
unbiased estimators \(c^T \beta_0\) are weakly approaching a tight family of normal
d.l.s
\[
L \left( \frac{(c^T \beta_0)^\wedge_n - c^T \beta_0}{\sqrt{c^T (\tilde{X}_h^T \tilde{X}_h)^+ c}} \right) \xrightarrow{\text{w.p.}} N_1(0, \sigma_n^2(c, \hat{x}_n)), \ n \to \infty, \quad (10)
\]
where
\[
\sigma_n^2(c, \hat{x}_n) = E \left( \frac{(c^T \beta_0)^\wedge_n - c^T \beta_0}{\sqrt{c^T (\tilde{X}_h^T \tilde{X}_h)^+ c}} \right)^2.
\]
If in addition HR\(_3\) holds then
\[
L(U_n^*(c, Y_n, \hat{x}_n^*) \mid Y_n) \xrightarrow{\text{w.p.}} L \left( \frac{(c^T \beta_0)^\wedge_n - c^T \beta_0}{\sqrt{c^T (\tilde{X}_h^T \tilde{X}_h)^+ c}} \right), \ n \to \infty. \quad (11)
\]
Relation (11) means that under the stated assumptions, the resampling
of weighted residuals gives consistency in asymptotic approximation of the
d.l. of normed deviations of the OLS-estimator \(c^T \beta_0\) in the case of linear
heteroscedastic regression. The assumptions stated in Theorem 3 also imply
convergence in uniform metric.

**Corollary 4.** If errors \(\{W_n\}_{h \geq 1}\) are independent, and assumptions HR\(_1\),
HR\(_2\) and HR\(_3\) hold then
\[
\sup_{z \in \mathbb{R}} \left| F_{U_n^*}(z \mid Y_n) - \Phi \left( \frac{z}{\sigma_n(c, \hat{x}_n)} \right) \right| \xrightarrow{P} 0, \ n \to \infty. \quad (12)
\]
4 Proofs

Lemma 1. If $A_1$ holds, then for any $\tau > 0$

\[(i) \max_{1 \leq h \leq n} |Y_{hn}(\tau)| \xrightarrow{P} 0, \quad (ii) \max_{1 \leq h \leq n} E[Y_{hn}(\tau)] \xrightarrow{} 0, \]

\[(iii) \max_{1 \leq h \leq n} |Y_{hn}^{\circ}(\tau)| \xrightarrow{P} 0, \quad (iv) \max_{1 \leq h \leq n} E[(Y_{hn}^{\circ}(\tau))^2] \xrightarrow{} 0, \quad n \to \infty. \quad (12)\]

Proof. Relation (12)(i) is fulfilled because for any $\tau > 0$

\[|Y_{hn}(\tau)| \leq |Y_{hn}|.\]

For $\tau > 0$ and any $\varepsilon < \tau$

\[E[Y_{hn}(\tau)] = E[Y_{hn}(\varepsilon)] + E[Y_{hn}(\varepsilon < |Y_{hn}| \leq \tau)].\]

Therefore,

\[| \max_{1 \leq h \leq n} E[Y_{hn}(\tau)] | \leq \varepsilon + \tau P\left[ \max_{1 \leq h \leq n} |Y_{hn}| > \varepsilon \right].\]

By $A_1$ for all sufficiently large $n \geq n(\varepsilon, \tau)$, we obtain $| \max_{1 \leq h \leq n} E[Y_{hn}(\tau)] | \leq 2\varepsilon$. We can take an arbitrary small $\varepsilon > 0$. Hence, (12)(ii) is valid. Relations (12) (iii) and (iv) can be proved similarly. □

Lemma 2. If $A_1$ and $A_2(\tau)$ hold, then the sequence of d.l.s $\{L(Y_{hn}^{\circ}(\tau))\}_{n \geq 1}$ is tight and

\[L(Y_{hn}^{\circ}(\tau)) \xrightarrow{w} L(Y_{n}^{\circ}(\tau)), \quad n \to \infty.\]

Proof. We have

\[Y_{hn}^{\circ}(\tau) = \sum_{h=1}^{n} Y_{hn}(\varepsilon < |Y_{hn}| \leq \tau),\]

and for the following events it holds that

\[\left\{ \max_{1 \leq h \leq n} |Y_{hn}| \leq \tau \right\} \subseteq \left\{ \sum_{h=1}^{n} Y_{hn}(\varepsilon < |Y_{hn}| \leq \tau) = 0 \right\}. \quad (13)\]

Therefore, we have

\[P\left[ \sum_{h=1}^{n} Y_{hn}(\varepsilon < |Y_{hn}| \leq \tau) = 0 \right] \geq P\left[ \max_{1 \leq h \leq n} |Y_{hn}| \leq \tau \right] \to 1, \quad n \to \infty.\]

It implies that $Y_{hn}^{\circ}(\tau) = Y_{n}^{\circ}(\tau) + o_p(1), \quad n \to \infty$. The desired result follows from Propositions 6 and 9. □
Lemma 3. If $A_1$ and $A_2(\tau)$ hold, then
\[ \sup_n \sigma_n^2(\tau) < \infty. \] (14)

Proof. Suppose on the contrary that $\lim_{n \to \infty} \sigma_n^2(\tau) = \infty$, i.e. there exists a subsequence $\{n_k\}_{k \geq 1}$ such that $\sigma_{n_k}(\tau) \to \infty$. For each $\{h, n\}$ and $\sigma^2_n(\tau) \neq 0$, we consider the normed r.v.s $Z^O_{hn_k}(\tau) = \frac{Y^O_{hn_k}(\tau)}{\sigma_{hn_k}(\tau)}$. We have from Lemma 1 that for all sufficiently large $n_k$
\[ \max_{1 \leq h \leq n_k} |Z^O_{hn_k}(\tau)| \leq \max_{1 \leq h \leq n_k} |Y^O_{hn_k}(\tau)| \to 0, \quad k \to \infty. \]

It follows that
\[(i) \quad \sum_{h=1}^{n_k} P[|Z^O_{hn_k}(\tau)| > \varepsilon] \to 0, \quad n \to \infty, \quad \text{for every } \varepsilon > 0; \]
In addition, we have
\[(ii) \quad \sum_{h=1}^{n_k} E[|Z^O_{hn_k}(\tau)|] = 0; \quad (iii) \quad \sum_{h=1}^{n_k} E[(Z^O_{hn_k}(\tau))^2] = 1, \quad k = 1, 2, \ldots. \]
Hence, by the Normal Convergence Criterion (Proposition 2) we have
\[ \mathcal{L}(Z^O_{hn_k}(\tau)) \overset{w}{\to} N_1(0, 1), \quad k \to \infty, \]
and for any $k$ such that $\sigma^2_{n_k}(\tau) > 0$, it follows that
\[ P[|Y^O_{hn_k}(\tau)| > \sigma_{n_k}(\tau)] = P[|Z^O_{hn_k}(\tau)| > 1] \to 1 - \frac{1}{\sqrt{2\pi}} \int_{-1}^{+1} e^{-x^2/2} dx > \frac{1}{4}; \quad k \to \infty. \]

For any large $m$ there exists $k(m)$ such that for all $k > k(m), \quad \sigma_{n_k}(\tau) > m$. Therefore, we have $P[|Y^O_{hn_k}(\tau)| > m] > 1/4$ for all sufficiently large $k$ and thus $\{\mathcal{L}(Y^O_{hn_k}(\tau))\}_{k \geq 1}$ is not tight. This contradicts the result of Lemma 2. Hence, (14) holds.

Lemma 4. Suppose that $A_1$ and $A_2(\tau_0)$ hold, for some $\tau_0 > 0$. Then $A_2(\tau)$ holds for any $\tau > 0$.

Proof. We have
\[ Y^O_{n}(\tau) = Y^O_{n}(\tau_0) + \sum_{h=1}^{n} \left( E[Y_{hn}I(|Y_{hn} | \leq \tau_0)] - E[Y_{hn}I(|Y_{hn} | \leq \tau)] \right). \] (15)
From $\mathbf{A}_1$ it follows that if $\tau < \tau_0$, then
\[ \left| \sum_{h=1}^{n} E[Y_{hn}I(\tau < |Y_{hn}| \leq \tau_0)] \right| \leq \tau_0 \sum_{h=1}^{n} P[|Y_{hn}| > \tau] \to 0 \quad n \to \infty. \quad (16) \]

If $\tau > \tau_0$, then we need only to write $\tau$ instead of $\tau_0$ and $\tau_0$ instead of $\tau$ in (16). Therefore, $Y_{\tau_n}^O(\tau) = Y_{\tau_n}^O(\tau_0) + o(1), \quad n \to \infty$, which implies $\mathbf{A}_2(\tau). \quad \square$

**Lemma 5.** If $\mathbf{A}_1$ holds, then for any $0 < \tau_1 < \tau_2 < \infty$ it follows that
\[ |\sigma_n^2(\tau_1) - \sigma_n^2(\tau_2)| \to 0, \quad n \to \infty. \quad (17) \]

**Proof.** We can write
\[
\sigma_n^2(\tau_1) - \sigma_n^2(\tau_2) \\
= \sum_{h=1}^{n} \left( E[(Y_{hn}^O(\tau_1))^2] - E[(Y_{hn}^O(\tau_2))^2] \right) = \sum_{h=1}^{n} E[Y_{hn}^2 I(\tau_1 < |Y_{hn}| \leq \tau_2)] \\
+ \sum_{h=1}^{n} E[Y_{hn} I(\tau_1 < |Y_{hn}| \leq \tau_2)] E[Y_{hn}(I(|Y_{hn}| \leq \tau_1) + I(|Y_{hn}| \leq \tau_2))].
\]

Here, we have
\[
\left| \sum_{h=1}^{n} E[Y_{hn}^2 I(\tau_1 < |Y_{hn}| \leq \tau_2)] \right| \leq \tau_2^2 \sum_{h=1}^{n} P[|Y_{hn}| > \tau_1] \to 0,
\]
\[
\left| \sum_{h=1}^{n} E[Y_{hn} I(\tau_1 < |Y_{hn}| \leq \tau_2)] E[Y_{hn}(I(|Y_{hn}| \leq \tau_1) + I(|Y_{hn}| \leq \tau_2))] \right| \leq \tau_2(\tau_1 + \tau_2) \sum_{h=1}^{n} P[|Y_{hn}| > \tau_1] \to 0, \quad n \to \infty.
\]

Hence, (17) holds. \quad \square

**Proof of Theorem 1. (Sufficiency of $\mathbf{A}_2(\tau)$).** As follows from Lemma 2, it is sufficient to prove that
\[ \mathcal{L}(Y_{\tau_n}^O(\tau)) \xrightarrow{w.a.} \mathcal{N}_1(0, \sigma_n^2(\tau)), \quad n \to \infty. \quad (18) \]

Let $f_{\tau_n}^O(t) = E[e^{itY_{\tau_n}^O(\tau)}]$. From Lemma 2 we know that $\{\mathcal{L}(Y_{\tau_n}^O(\tau))\}_{n \geq 1}$ is tight. Then, the Continuity Theorem (Proposition 7) states that it is sufficient to check that for each $t \in \mathbb{R}^1$
\[ f_{\tau_n}^O(t) - e^{-t^2\sigma_n^2(\tau)/2} \to 0, \quad n \to \infty. \quad (19) \]

11
We need the following elementary inequality
\[
\left| e^{iz} - 1 - iz + \frac{1}{2} z^2 \right| \leq |z|^3, \quad z \in \mathbb{R}^1.
\] (20)

Note that (12) (iii) implies that for arbitrary small \( \varepsilon > 0 \)
\[
\sum_{h=1}^{n} P[|Y_{hn}(\tau)| > \varepsilon(n)] \rightarrow 0, \quad n \rightarrow \infty.
\] (21)

From (21) it follows that there is a sequence \( \varepsilon(n) \rightarrow 0 \) such that
\[
\sum_{h=1}^{n} P[|Y_{hn}(\tau)| > \varepsilon(n)] \rightarrow 0, \quad n \rightarrow \infty.
\] By applying the inequality
\[
E[|Y_{hn}(\tau)|^3] \leq \sigma_{hn}^2 |\varepsilon(n)| + (2\tau)^3 P[|Y_{hn}(\tau)| > \varepsilon(n)].
\] (22)

Therefore, from (14), (21) and (22) we have
\[
\sum_{h=1}^{n} E[|Y_{hn}(\tau)|^3] = o(1), \quad n \rightarrow \infty.
\] (23)

Then inequalities (20) and (23) imply that
\[
f_{\tau \cdot n}(t) = E[e^{itY_{hn}(\tau)}] = 1 - \frac{t^2}{2} \sigma_{hn}^2 + r_{\tau \cdot n}(t),
\] (24)

where \( |r_{\tau \cdot n}(t)| \leq t^3 E[|Y_{hn}(\tau)|^3] \). From (23), (24) and (14) for any \( t \in \mathbb{R}^1 \) we have
\[
f_{\tau \cdot n}(t) = \prod_{h=1}^{n} f_{\tau \cdot h}(t) = e^{-t^2 \sigma_{hn}^2/2} + o(1), \quad n \rightarrow \infty.
\] (25)

We do not exclude the case when \( \sigma_{hn}^2(\tau) \rightarrow 0 \), because then both \( f_{\tau \cdot n}(t) \rightarrow 1 \) and \( e^{-t^2 \sigma_{hn}^2(\tau)/2} \rightarrow 1, \quad n \rightarrow \infty \). Relation (19) follows from (25). Hence, (2) holds. Sufficiency of \( \mathbf{A}_2(i) \) is proved.

(Necessity of \( \mathbf{A}_2(\tau) \)). The family of normal d.l.s. \( \{N_1(0, \sigma_n^2)\}_{n \geq 1} \) is tight because \( \sigma_+^2 < \infty \). Hence, Proposition 6 and (2) imply that \( \mathbf{A}_2(\tau) \) holds. \( \square \)

Lemma 6. If \( \mathbf{A}_1 \) and \( \mathbf{A}_2(\tau) \) hold then
\[
\sum_{h=1}^{n} Y_{hn}(\tau) E[Y_{hn}(\tau)] \xrightarrow{P} 0, \quad n \rightarrow \infty.
\] (26)
Proof. The r.v.s \( \tilde{Z}_{hn}(\tau) = Y_{hn}^o(\tau)E[Y_{hn}(\tau)] \) satisfy the following assumptions of the Degenerate Convergence Criterion (Proposition 1):

(i) \( \max_{1 \leq h \leq n} |\tilde{Z}_{hn}(\tau)| \leq \tau \max_{1 \leq h \leq n} |Y_{hn}^o(\tau)| \xrightarrow{P} 0, \quad n \to \infty; \)

(ii) \( \sum_{h=1}^{n} E[\tilde{Z}_{hn}(\tau)] = 0; \)

(iv) \( \text{Var} \left[ \sum_{h=1}^{n} \tilde{Z}_{hn}(\tau) \right] = \sum_{h=1}^{n} E[(Y_{hn}^o(\tau))^2](E[Y_{hn}(\tau)])^2 \leq \max_{1 \leq h \leq n}(E[Y_{hn}(\tau)])^2 \sigma_n^2(\tau) \xrightarrow{P} 0, \quad n \to \infty, \)

by Lemmas 1 and 3. Hence, (26) holds.

Lemma 7. If \( A_1 \) and \( A_2(\tau) \) hold, then as \( n \to \infty \)

\[
\sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 = \sum_{h=1}^{n} (Y_{hn}^o(\tau))^2 + \sum_{h=1}^{n} (E[Y_{hn}(\tau)])^2 - \frac{1}{n} \left( \sum_{h=1}^{n} E[Y_{hn}(\tau)] \right)^2 + o_P(1). (27)
\]

Proof. It is easy to check the following relation:

\[
\sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 = \sum_{h=1}^{n} (Y_{hn}^o(\tau))^2 + \sum_{h=1}^{n} (E[Y_{hn}(\tau)])^2 - \frac{1}{n} \left( \sum_{h=1}^{n} Y_{hn}(\tau) \right)^2 - \frac{1}{n} (Y_{n}^o(\tau))^2 - \frac{2}{n} Y_{n}^o(\tau)E[Y_{n}(\tau)] + 2 \sum_{h=1}^{n} Y_{hn}^o(\tau)E[Y_{hn}(\tau)]. (28)
\]

From the tightness of \( \{L(Y_{n}^o(\tau))\}_{n \geq 1} \) proved in Lemma 2, it follows that \( \frac{1}{n}(Y_{n}^o(\tau))^2 \xrightarrow{P} 0, \quad n \to \infty. \) From (12) (ii) we have that

\[
\left| \frac{1}{n} Y_{n}^o(\tau)E[Y_{n}(\tau)] \right| \leq \frac{1}{n} |Y_{n}^o(\tau)| \max_{1 \leq h \leq n} |E[Y_{hn}(\tau)]| \xrightarrow{P} 0, \quad n \to \infty.
\]

The last term in (28) also converges to zero as was shown in Lemma 6. \( \square \)

Lemma 8. If \( A_1 \) and \( A_2(\tau) \) hold, then

\[
\sum_{h=1}^{n} (Y_{hn}^o(\tau))^2 - \sum_{h=1}^{n} E[(Y_{hn}^o(\tau))^2] \xrightarrow{P} 0, \quad n \to \infty. (29)
\]
Proof. We can consider \( \{\sigma^2_n(\tau)\}_{n \geq 1} \) as a union of converging subsequences \( \{\sigma^2_{n_k}(\tau)\}_{k \geq 1} \). We consider case 1 with a subsequence \( \{n_k\}_{k \geq 1} \) such that \( \lim_{k \to \infty} \sigma^2_{n_k}(\tau) = 0, k \to \infty \), and case 2 with a subsequence \( \{n_k\}_{k \geq 1} \) such that \( \lim_{k \to \infty} \sigma^2_{n_k}(\tau) > 0. \) Recall that the set of all limit points \( \{\sigma^2_{\infty}(\tau)\} : \exists \{n_k\}_{k \geq 1}, \sigma^2_{\infty}(\tau) = \lim_{k \to \infty} \sigma^2_{n_k}(\tau) \) is bounded, \( \sigma^2_{\infty}(\tau) \leq \sigma^2_{\ast} \).

Case 1. We have \( \mathbb{E}[\sum_{h=1}^{n_k} (Y^\circ_{hn_k}(\tau))^2] = \sigma^2_{n_k}(\tau) \to 0, n \to \infty. \) Hence, \( \sum_{h=1}^{n_k} (Y^\circ_{hn_k}(\tau))^2 \xrightarrow{P} 0, n_k \to \infty, \) and (29) holds with \( n = n_k, k \to \infty. \)

Case 2. Here, from Proposition 2 we have \( \mathbb{L}(Y^\circ_{n_k}(\tau)/\sigma_{n_k}) \xrightarrow{w} \mathcal{N}_1(0, 1). \) Therefore, by the Raikov theorem (Proposition 4) we have \( \sum_{h=1}^{n_k} \left( \frac{Y^\circ_{hn_k}(\tau)}{\sigma_{n_k}(\tau)} \right)^2 - 1 \xrightarrow{P} 0, n \to \infty. \) Here, for a \( \delta > 0 \) and all sufficiently large \( k, \delta < \sigma^2_{n_k}(\tau) \leq \sigma^2_{\ast} \). Therefore this relation is equivalent to (29). Hence, (29) holds for every limit point \( \sigma^2_{\infty}(\tau). \)

Lemma 9. If \( A_1 \) and \( A_2(\tau) \) hold, then

\[
\mathcal{L}(Y^\ast_n | X_n) \xrightarrow{w(\tau)} \mathcal{L}(Y^\ast_n(\tau) | X_n), \quad n \to \infty. \tag{30}
\]

Proof. From (1) we have

\[
Y^\ast_n - Y^\ast_n(\tau) = \sum_{h=1}^{n} (N^\ast_{hn} - 1)(Y_{hn} - Y_{hn}(\tau)) = \sum_{h=1}^{n} (N^\ast_{hn} - 1)Y_{hn}I(| Y_{hn} | > \tau). \tag{31}
\]

We can evaluate (31) as follows:

\[
| Y^\ast_n - Y^\ast_n(\tau) | \leq (n - 1) \sum_{h=1}^{n} | Y_{hn} | I(| Y_{hn} | > \tau).
\]

From (13) we obtain that

\[
P[(n - 1) \sum_{h=1}^{n} | Y_{hn} | I(| Y_{hn} | > \tau) = 0] \geq P[\max_{1 \leq h \leq n} | Y_{hn} | \leq \tau] \to 1, \quad n \to \infty.
\]

Hence, \( P[Y^\ast_n = Y^\ast_n(\tau)] \to 1, n \to \infty. \) It implies that for every \( \varepsilon > 0 \) and each continuous and bounded \( f(\cdot), \) i.e. \( f(\cdot) \in \mathcal{C}_b(\mathbb{R}^1), \)

\[
| \mathbb{E}^*[f(Y^\ast_n) | X_n] - \mathbb{E}^*[f(Y^\ast_n(\tau)) | X_n] | \leq 2 \sup_{z \in \mathbb{R}^1} | f(z) | P[Y^\ast_n \neq Y^\ast_n(\tau)] \to 0,
\]

\( n \to \infty. \) Therefore, (30) holds as corresponding to Definition 4 of conditional d.l.s weakly approaching in probability. \( \square \)
Proof of Theorem 2. (Sufficiency of $A_3(\tau)$). Suppose that $A_1, A_2(\tau)$ and $A_3(\tau)$ hold. From Theorem 1 and Lemma 2 we have that $\mathcal{L}(Y_n^\circ(\tau)) \xrightarrow{w} N_1(0, \sigma_n^2(\tau)), n \to \infty$. The main idea of the proof is to show that

$$\mathcal{L}(Y_n^\circ(\tau) \mid X_n) \xrightarrow{w(P)} N_1(0, \sigma_n^2(\tau)), n \to \infty.$$  \hfill (32)

Then, due to the transitivity of d.l.s weakly approaching in probability, it follows that

$$\mathcal{L}(Y_n^\circ(\tau) \mid X_n) \xrightarrow{w(P)} \mathcal{L}(Y_n^\circ(\tau)), n \to \infty,$$  \hfill (33)

and then (3) follows by Lemma 9. The sequences of d.l.s $\{\mathcal{L}(Y_n^\circ(\tau))\}_{n \geq 1}$ and $\{N_1(0, \sigma_n^2(\tau))\}_{n \geq 1}$ are tight. Therefore, we can apply the Continuity Theorem for sequences of random d.l.s weakly approaching in probability (Proposition 8). We need to use the ch.f.s $f^{\circ\circ}_{\tau,n}(t \mid X_n) = E[e^{itY_n^\circ(\tau)} \mid X_n]$. Each resampling copy of $Y_n^\circ(\tau)$ is obtained by $n$ independent samplings from the components of the list $Y_n^\circ(\tau)$, where each of the $n$ components is selected with probability $1/n$. Therefore, we have

$$f^{\circ\circ}_{\tau,n}(t \mid X_n) = \left(\frac{1}{n} \sum_{h=1}^{n} e^{it(Y_{hn}(\tau) - \bar{Y}_n(\tau))}\right)^n$$

$$= \left(1 - \frac{t^2}{2n} \sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 + R_n(t, \tau)\right)^n,$$  \hfill (34)

where

$$R_n(t, \tau) = \frac{1}{n} \sum_{h=1}^{n} \left(e^{it(Y_{hn}(\tau) - \bar{Y}_n(\tau))} - 1 - it(Y_{hn}(\tau) - \bar{Y}_n(\tau))\right) + \frac{t^2}{2} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2.$$  \hfill (35)

We evaluate $R_n(t, \tau)$ with the help of inequality (20)

$$|R_n(t, \tau)| \leq \frac{t^3}{n} \sum_{h=1}^{n} |Y_{hn}(\tau) - \bar{Y}_n(\tau)|^3$$

$$\leq \frac{t^3}{n} \sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 \max_{1 \leq h \leq n} |Y_{hn}(\tau)|.$$  \hfill (36)
Therefore, by Lemma 1 \( | R_n(t, \tau) | = o_p \left( \frac{\tau^2}{2n} \sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 \right) \), and additionally from Lemmas 7 and 8 it follows that

\[
\sum_{h=1}^{n} (Y_{hn}(\tau) - \bar{Y}_n(\tau))^2 = \sigma_n^2(\tau)
\]

\[
+ \sum_{h=1}^{n} \left( E[Y_{hn}(\tau)] \right)^2 - \frac{1}{n} \left( \sum_{h=1}^{n} E[Y_{hn}(\tau)] \right)^2
\] + \(o_p(1), \ n \to \infty. \quad (37)

Recall that \( \sigma_n^2(\tau) \leq \sigma^2 < \infty \) and assume that \( A_3(\tau) \) holds. Hence, from (34) - (37) we obtain

\[ f_{\tau-n}^\circ(t \mid X_n) - e^{-t^2 \sigma_n^2(\tau)/2} \xrightarrow{P} 0, \ n \to \infty. \]

Proposition 8 implies (32). Then (33) holds. Therefore, \( A_3(\tau) \) is sufficient for (3).

**Necessity of \( A_3(\tau) \)**. Suppose that resampling gives us a consistent estimator of \( L(Y_{n}^\circ(\tau)) \), i.e. (3) holds. Then, from Lemmas 2 and 9 we have

\[ L(Y_{n}^\circ(\tau) \mid X_n) \xrightarrow{w(a)} L(Y_{n}^\circ(\tau)), \ n \to \infty. \quad (38) \]

From (38), Theorem 1 and Lemma 2 we obtain

\[ L(Y_{n}^\circ(\tau) \mid X_n) \xrightarrow{w(a)} N_1(0, \sigma_n^2(\tau)), \ n \to \infty. \quad (39) \]

We know that \( \sigma_n^2(\tau) \leq \sigma^2 < \infty \). Hence, the sequence of d.l.s \( \{N_1(0, \sigma_n^2(\tau))\}_{n \geq 1} \) is tight. Then from (39), and by the Continuity Theorem for d.l.s weakly approaching in probability (Proposition 8), it follows that for every \( t \in \mathbb{R}^2 \)

\[ f_{\tau-n}^\circ(t \mid X_n) - e^{-t^2 \sigma_n^2(\tau)/2} \xrightarrow{P} 0, \ n \to \infty. \quad (40) \]

From Lemma 8 for every \( t \in \mathbb{R}^1 \), we have

\[ e^{-t^2 \sigma_n^2(\tau)/2} - e^{-t^2 \sum_{h=1}^{n} (Y_{hn}(\tau))^2/2} \xrightarrow{P} 0, \ n \to \infty. \quad (41) \]

From (27), (34), and (35), which hold under assumptions \( A_1 \) and \( A_2(\tau) \), it follows that for every \( t \in \mathbb{R}^1 \)

\[ f_{\tau-n}^\circ(t \mid X_n) = \exp \left\{ -\frac{t^2}{2} \left( \sum_{h=1}^{n} (Y_{hn}(\tau))^2 + W_n(\tau) \right) \right\} + o_p(1), \ n \to \infty, \]
where
\[ W_n(\tau) = \sum_{h=1}^{n} (E[Y_{hn}(\tau)])^2 - \frac{1}{n} \left( \sum_{h=1}^{n} E[Y_{hn}(\tau)] \right)^2 \geq 0. \tag{42} \]

From (29), (40), (41) and (42) we obtain
\[ f_{\tau,n}(t \mid X_n) - e^{-t^2\sigma_n^2(\tau)/2} = e^{-t^2\sum_{h=1}^{n} (Y_{hn}(\tau))^2/2}(e^{-t^2W_n(\tau)/2} - 1) + o_p(1) \xrightarrow{P} 0, \quad n \to \infty. \]

Hence, \( W_n(\tau) \to 0, \quad n \to \infty, \) i.e. \( A_3(\tau) \) holds. \( \square \)

**Proof of Corollary 1 and Corollary 2.** Proofs follow directly from Proposition 10, because \( \lim_{n \to \infty} \sigma_n^2(\tau) > 0, \) together with uniform boundness \( \sigma_n^2(\tau) \leq \sigma_n^2 < \infty, \) imply that all \( N_1(0, \sigma_n^2(\tau)) \) have uniformly bounded densities \( \frac{1}{\sqrt{2\pi\sigma_n(\tau)}} e^{-x^2/(2\sigma_n^2(\tau))}. \) Hence, the family of normal d.f.s is uniformly continuous and we can apply Proposition 10. \( \square \)

**Proof of Corollary 3.** From the Chebyshev inequality and (4) it follows that for every \( \tau > 0 \)
\[ \sum_{h=1}^{n} P[|Y_{hn}| > \tau] \leq \frac{1}{\tau^2} \sum_{h=1}^{n} E[Y_{hn}^2 I(|Y_{hn}| > \tau)] \to 0, \quad n \to \infty. \]

Hence, \( A_1 \) holds. We will use the following inequalities
\[ \tau I(|Y_{hn}| > \tau) \leq |Y_{hn}|, \tag{43} \]
\[ |E[Y_{hn} I(|Y_{hn}| \leq \tau)]|E[Y_{hn} I(|Y_{hn}| > \tau)]| \leq E[Y_{hn}^2 I(|Y_{hn}| > \tau)]. \tag{44} \]

From (4) and (43) we obtain
\[ \left| \sum_{h=1}^{n} E[Y_{hn} I(|Y_{hn}| > \tau)] \right| \leq \frac{1}{\tau} \sum_{h=1}^{n} E[Y_{hn}^2 I(|Y_{hn}| > \tau)] \to 0, \quad n \to \infty. \tag{45} \]

We have
\[ \sigma_n^2 - \sigma_n^2(\tau) = \sum_{h=1}^{n} \left( E[Y_{hn}^2 I(|Y_{hn}| > \tau)] - (E[Y_{hn} I(|Y_{hn}| > \tau)])^2 \right)^2 \]
\[ - 2E[Y_{hn} I(|Y_{hn}| \leq \tau)]E[Y_{hn} I(|Y_{hn}| > \tau)] \right). \tag{46} \]

The Jensen inequality, (4), (44) and (46) imply that
\[ |\sigma_n^2 - \sigma_n^2(\tau)| \leq 3 \sum_{h=1}^{n} E[Y_{hn}^2 I(|Y_{hn}| > \tau)] \to 0, \quad n \to \infty. \tag{47} \]
From (45) we have
\[ Y_n^\circ = Y_n^\circ(\tau) - \sum_{h=1}^{n} E[Y_{hn}I(|Y_{hn}| > \tau)] = Y_n^\circ(\tau) + \sum_{h=1}^{n} Y_{hn}I(|Y_{hn}| > \tau) \]
\[ - \sum_{h=1}^{n} E[Y_{hn}I(|Y_{hn}| > \tau)] = Y_n^\circ(\tau) + o_p(1), \quad n \to \infty. \quad (48) \]

From assumption \( \sum_{h=1}^{n} E[Y_{hn}^2] \leq C_2 \) and (48) we have that the sequences of d.l.s \( \{ L(Y_n^\circ) \}_{n \geq 1}, \{ L(Y_n^\circ(\tau)) \}_{n \geq 1}, \) and \( \{ L(Y_n^\circ(\tau)) \}_{n \geq 1}, \) are tight. Hence, \( A_2(\tau) \) holds. From (48), Proposition 9, (18) and (47) we obtain (5).

For every \( \tau > 0 \) we have
\[ \sum_{h=1}^{n} (E[Y_{hn}(\tau)])^2 = \sum_{h=1}^{n} (E[Y_{hn}] - E[Y_{hn}I(|Y_{hn}| > \tau)])^2 \]
\[ \leq 2 \sum_{h=1}^{n} (E[Y_{hn}])^2 + 2 \sum_{h=1}^{n} E[Y_{hn}^2]P[\max_{1 \leq h \leq n} |Y_{hn}| > \tau] \]
\[ \leq 2 \sum_{h=1}^{n} (E[Y_{hn}])^2 + 2C_2P[\max_{1 \leq h \leq n} |Y_{hn}| > \tau] \to 0, \quad n \to \infty. \]

Therefore, we have that \( A_2(\tau) \) and \( A_3(\tau) \) hold for every \( \tau \).

Then (33) and (48) imply
\[ L(Y_n^\circ(\tau)) \xrightarrow{wa(P)} N(0, \sigma_n^2), \quad n \to \infty. \quad (49) \]

We can write the following identity
\[ Y_n^\circ = Y_n^\circ(\tau) + \sum_{h=1}^{n} (N_{hn}^* - 1)Y_{hn}I(|Y_{hn}| > \tau). \quad (50) \]

We can evaluate the second moment of the sum in (50) as follows
\[ E \left[ E^* \left( \sum_{h=1}^{n} (N_{hn}^* - 1)Y_{hn}I(|Y_{hn}| > \tau) \right)^2 | X_n \right] \]
\[ = E \left[ \sum_{h=1}^{n} \left( 1 - \frac{1}{n} \right) Y_{hn}^2I(|Y_{hn}| > \tau) \right] \]
\[
- \frac{1}{n} \sum_{h_1=1}^{n} \sum_{h_2=1 \atop h_1 \neq h_2}^{n} \prod_{i=1, 2} Y_{h_i n} I(|Y_{h_i n}| > \tau)
\]
\[
= E \left[ \sum_{h=1}^{n} Y_{h n}^2 I(|Y_{h n}| > \tau) \right] - \frac{1}{n} \left( \sum_{h=1}^{n} Y_{h n} I(|Y_{h n}| > \tau) \right)^2
\]
\[
\leq E \left[ \sum_{h=1}^{n} Y_{h n}^2 I(|Y_{h n}| > \tau) \right] \to 0, \quad n \to \infty.
\]

Therefore, we have

\[ Y_{n}^{\circ} = Y_{n}^{\circ}(\tau) + o_P(1), \quad n \to \infty. \quad (51) \]

The desired result (6) follow from (51), Proposition 9, (49) and (50).

Proof of Theorem 3. We can consider the triangular array of r.v.s

\[ X_{hn} = c^T (\tilde{X}_n^T \tilde{X}_n) + \tilde{x}_h W_h, \quad c^T \in \mathcal{M}(\tilde{X}_n^T), \]

where \( W_h, \ h = 1, \ldots, n, \) are (unobserved) errors in (7). Let \( \rho_n = (c^T (\tilde{X}_n^T \tilde{X}_n) + \tilde{x}_h)^{1/2} \) and \( Y_{h n} = \frac{1}{\rho_n} X_{hn}, \ \{h, n\} \in \mathcal{T}. \)

Then the normed deviations of OLS-estimators can be written as follows

\[
S_n(c, W_n, \tilde{X}_n) = \frac{1}{\rho_n} \sum_{h=1}^{n} (N_{h n}^* - \tilde{x}_h W_h).
\]

From HR2 it follows that \( E[Y_{hn}] = 0, \) i.e. \( Y_{hn}^\circ = Y_{hn}. \) Relation (4) follows from HR1. Assumption HR2 and (8) imply that

\[
\sigma_n^2(c, \tilde{X}_n) = E[(S_n(c, W_n, \tilde{X}_n))^2] = \sum_{h=1}^{n} E[Y_{hn}^2]
\]

\[
= \sum_{h=1}^{n} \sigma_h^2 (\tilde{x}_h) c^T (\tilde{X}_n^T \tilde{X}_n) c + \tilde{x}_h \tilde{x}_h^T (\tilde{X}_n^T \tilde{X}_n)^2 + c^T (\tilde{X}_n^T \tilde{X}_n)^2 c \leq \sigma_n^2. \quad (53)
\]

Therefore, all assumptions, stated in Corollary 3, are fulfilled for the r.v.s \( \{Y_{hn}\}. \) Hence, (5) is valid and it is equivalent to (10).

In order to prove (11) we consider

\[
S_n^*(c, W_n, \tilde{X}_n) = \sum_{h=1}^{n} (N_{h n}^* - 1) \frac{c^T (\tilde{X}_n^T \tilde{X}_n) + \tilde{x}_h}{c^T (\tilde{X}_n^T \tilde{X}_n) + c} W_h. \quad (54)
\]

Relations (5) and (6) in Corollary 3 imply

\[
\mathcal{L}(S_n^*(c, W_n, \tilde{X}_n) \mid W_n) \overset{\text{weak}}{\longrightarrow} N_1(0, \sigma_n^2(c, \tilde{X}_n)), \quad n \to \infty. \quad (55)
\]
We are not able to use (54) and (55) because the errors \( W_1, \ldots, W_n \) are not observable.

We can realize resamplings from the list of residuals as written in (9). We have

\[
Y_h - \hat{Y}_h = W_h - \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n.
\]

From (9) and (56) we obtain the following relation:

\[
U_n^*(c, Y_n, \hat{x}_n) = S_n^*(c, W_n, \hat{x}_n) - V_n^*(c, W_n, \hat{x}_n),
\]

where

\[
V_n^*(c, W_n, \hat{x}_n) = \sum_{h=1}^{n} (N_{hn}^* - 1) \frac{c^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_h \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n}{\sqrt{c^T (\hat{x}_n^T \hat{x}_n) + c}}.
\]

We will prove that \( V_n^*(c, W_n, \hat{x}_n) \) converges in probability to zero.

Note, that \( \text{E}^*[\left( N_{hn}^* - 1 \right)^2] = 1 - 1/n, \) \( \text{E}^*[\left( N_{h1n}^* - 1 \right)(N_{h2n}^* - 1)] = -1/n \) and \( \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T \text{E}[W_n W_n^T X_n (\hat{x}_n^T \hat{x}_n)] + \hat{x}_h \leq \sigma^2 (\hat{x}_h^T (\hat{x}_n^T \hat{x}_n)) + \hat{x}_h. \)

We can evaluate the second moment of \( V_n^*(c, W_n, \hat{x}_n) \) in two steps. We start evaluating the conditional expectation given \( W_n \) and after that we take the expectation related to \( W_n \), and then we use (8). We have

\[
\text{E}^*[\left( V_n^*(c, W_n, \hat{x}_n) \right)^2 | W_n]
\]

\[
= \sum_{h=1}^{n} \text{E}^*[\left( N_{hn}^* - 1 \right)^2] \left( \frac{c^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_h \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n}{\sqrt{c^T (\hat{x}_n^T \hat{x}_n) + c}} \right)^2
\]

\[
- \sum_{h_1=1}^{n} \sum_{h_2=1, h_1 \neq h_2}^{n} \text{E}^*[\left( N_{h1n}^* - 1 \right)(N_{h2n}^* - 1)]
\]

\[
\prod_{j=1,2} \left( \frac{c^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_h \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n}{\sqrt{c^T (\hat{x}_n^T \hat{x}_n) + c}} \right)
\]

\[
= \sum_{h=1}^{n} \left( \frac{c^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_h \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n}{\sqrt{c^T (\hat{x}_n^T \hat{x}_n) + c}} \right)^2
\]

\[
- \frac{1}{n} \left( \sum_{h=1}^{n} \left( \frac{c^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_h \hat{x}_h^T (\hat{x}_n^T \hat{x}_n) + \hat{x}_n^T W_n}{\sqrt{c^T (\hat{x}_n^T \hat{x}_n) + c}} \right)^2 \right).
\]

20
From (8) and HR3 it follows that

$$E\left[ E^*\left( (V^*_n(c, W_n, \tilde{X}_n))^2 \mid W_n \right) \right]$$

$$\leq \sum_{h=1}^{n} c^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ x_h x_h^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ \tilde{x}_h \tilde{x}_h^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ c$$

$$\leq \sigma^2 + \sum_{h=1}^{n} \left( c^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ x_h \right)^2 x_h^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ x_h$$

$$\leq r^2 \sigma^2 n \frac{\|c\|^2 \left( \text{tr} \left( \tilde{X}_n^T \tilde{X}_n \right) \right)^3}{c^T \left( \tilde{X}_n^T \tilde{X}_n \right)^+ c} \to 0, \quad n \to \infty.$$
Definition 1. A sequence of d.l.s \( \{ L(T_n) \}_{n \geq 1} \) is called tight if for any \( \varepsilon > 0 \) there exists a constant \( C_\varepsilon > 0 \) such that
\[
\sup_n P[|T_n| > C_\varepsilon] < \varepsilon.
\]

Definition 2. Let \( T_0 \) be an r.v. such that for each \( f(\cdot) \in \mathcal{C}_b(\mathbb{R}^1) \)
\[
E[f(T_n)] \to E[f(T_0)], \quad n \to \infty.
\]
Then, the sequence of d.l.s \( \{ L(T_n) \}_{n \geq 1} \) is called weakly converging to \( L(T_0) \).

In short we write
\[
L(T_n) \xrightarrow{w} L(T_0), \quad n \to \infty.
\]

Below we let \( X'_{hn}(\tau) = X'_{hn} \mathbb{1}(|X'_{hn}| \leq \tau) \).

Remark. The relations \( \sum_{h=1}^{n} P[|X'_{hn}| > \varepsilon] \to 0, \) and \( \max_{1 \leq h \leq n} |X'_{hn}| \xrightarrow{P} 0, \quad n \to \infty, \) are equivalent for the independent r.v.s \( X'_{1n}, \ldots, X'_{nm} \).

Proposition 1. (The Degenerate Convergence Criterion). For every \( \varepsilon > 0 \)
\[
\max_{1 \leq h \leq n} P[|X'_{hn}| > \varepsilon] \to 0, \quad n \to \infty, \quad \text{and} \quad L(X'_n) \xrightarrow{w} L(0), \quad n \to \infty, \quad \text{if and only if for every} \quad \varepsilon > 0 \quad \text{and a} \quad \tau > 0
\]
(i) \( \sum_{h=1}^{n} P[|X'_{hn}| > \varepsilon] \to 0, \)
(ii) \( \sum_{h=1}^{n} E[X'_{hn}(\tau)] \to 0, \)
(iii) \( \sum_{h=1}^{n} (E[X'_{hn}^2(\tau)] - (E[X'_{hn}(\tau)])^2) \to 0, \quad \text{as} \quad n \to \infty. \)

Proposition 2. (The Normal Convergence Criterion). For every \( \varepsilon > 0 \)
\[
\max_{1 \leq h \leq n} P[|X'_{hn}| > \varepsilon] \to 0, \quad n \to \infty, \quad \text{and} \quad L(X'_n) \xrightarrow{w} \mathcal{N}_1(\mu, \sigma^2), \quad n \to \infty, \quad \text{if and only if for every} \quad \varepsilon > 0 \quad \text{and a} \quad \tau
\]
(i) \( \sum_{h=1}^{n} P[|X'_{hn}| > \varepsilon] \to 0, \)
(ii) \( \sum_{h=1}^{n} E[X'_{hn}(\tau)] \to \mu, \)
(iii) \( \sum_{h=1}^{n} (E[X'_{hn}^2(\tau)] - (E[X'_{hn}(\tau)])^2) \to \sigma^2 \quad \text{as} \quad n \to \infty. \)

Proposition 3. Suppose that there is a limit d.l. \( L(X'_0) \) of an r.v. \( X'_0 \),
such that \( L(X'_n) \xrightarrow{w} L(X'_0), \quad n \to \infty \). Then \( L(X'_0) = \mathcal{N}_1(\mu, \sigma^2) \) and for every \( \varepsilon > 0 \quad \max_{1 \leq h \leq n} P[|X'_{hn}| > \varepsilon] \to 0, \quad n \to \infty \), if and only if
\[
\max_{1 \leq h \leq n} |X'_{hn}| \xrightarrow{P} 0, \quad n \to \infty.
\]

Proofs of Propositions 1, 2 and 3 are given in Loève (1977), pp. 328-329.

Proposition 4. (The Rajkov theorem). Let \( X' = \{ X'_{hn} : \{ h, n \} \in \mathcal{I} \} \) be
a triangular array. If for every \( \varepsilon > 0 \quad \max_{1 \leq h \leq n} P[|X'_{hn}| > \varepsilon] \to 0 \) as \( n \to \infty \), then the following two statements are equivalent:
(i) there exists a sequence \(\{u_n\}_{n \geq 1}\) such that 
\[
L(X_n' - u_n) \xrightarrow{w} N_1(0, 1), \quad n \to \infty;
\]
(ii) \[
\sum_{h=1}^{n} (X_{hn}'(\tau))^2 \xrightarrow{P} 1, \quad n \to \infty,
\]
where \(X_{hn}' = X_{hn}' - \mathbb{E}[X_{hn}' | X_{hn}' \leq \tau]\).

**Proof.** See Theorem 5 on p. 143 in Gnedenko and Kolmogorov (1968).

**Proposition 5.** (The Prokhorov theorem). If a sequence of d.l.s \(\{L(T_n)\}_{n \geq 1}\) is tight, then there exists a subsequence \(\{L(T_{nk})\}_{k \geq 1}\) and an r.v. \(T_0\) such that 
\[
L(T_{nk}) \xrightarrow{w} L(T_0), \quad n \to \infty.
\]

**Proof.** is given in Shiryaev (1996).

The following definition eliminates the necessity to assume the existence of a limit d.l.

**Definition 3.** Let \(\{L(T_n')\}_{n \geq 1}\) and \(\{L(T_n'')\}_{n \geq 1}\) be two sequences of d.l.s. They are said to be weakly approximating (each other) if for every \(f(\cdot) \in \mathcal{B}(\mathbb{R}^1)\)
\[
\mathbb{E}[f(T_n')] - \mathbb{E}[f(T_n'')] \to 0, \quad n \to \infty.
\]
In short we write \(L(T_n') \xrightarrow{wa} L(T_n''), n \to \infty\).

Note that if \(T_n'' \equiv T_0\) then Definition 3 is reduced to weak convergence.

**Proposition 6.** If \(L(T_n') \xrightarrow{wa} L(T_n''), n \to \infty\), and \(\{L(T_n'')\}_{n \geq 1}\) is tight, then \(\{L(T_n')\}_{n \geq 1}\) is also tight.

**Proof.** See Lemma 5, pp. 817 - 818 in Belyaev and Sjöstedt-de Luna (2000).

**Definition 4.** Let \(\{T_n', T_n''\}_{n \geq 1}\) be r.v.s defined for each \(n\) on the same probability space as \(X_n'\). Then, the sequences \(\{L(T_n' | X_n')\}_{n \geq 1}\) and \(\{L(T_n'' | X_n')\}_{n \geq 1}\) of conditional d.l.s, given \(X_n'\), are said to be weakly approximating (each other) in probability along \(X_n'\) if for every function \(f(\cdot) \in \mathcal{B}(\mathbb{R}^1)\)
\[
\mathbb{E}[f(T_n') | X_n'] - \mathbb{E}[f(T_n'') | X_n'] \xrightarrow{P} 0, \quad n \to \infty.
\]
In short we write 
\[
L(T_n' | X_n') \xrightarrow{wa(P)} L(T_n'' | X_n'), \quad n \to \infty.
\]
In the case when, instead of $\mathcal{L}(T''_n | X'_n)$ and $E[f(T''_n) | X'_n]$, we have $\mathcal{L}(T''_n)$ and $E[f(T''_n)]$, respectively, then instead of (59), we write

$$\mathcal{L}(T''_n) \xrightarrow{\text{wa}(P)} \mathcal{L}(T'_{n}), \quad n \to \infty.$$  

Let $f_n(t) = E[e^{itT'_n}]$, $f_n(t | X'_n) = E[e^{itT'_n} | X'_n]$, and $g_n(t) := E[e^{itT''_n}]$ be the characteristic functions of $T'_n, T''_n$ given $X'_n$, and $T''_n$.

**Proposition 7.** (The Continuity Theorem for weakly approaching sequences of d.l.s). Let $\{\mathcal{L}(T''_n)\}_{n \geq 1}$ and $\{\mathcal{L}(T'_{n})\}_{n \geq 1}$ be two sequences of d.l.s where $\{\mathcal{L}(T''_n)\}_{n \geq 1}$ is tight. Then

$$\mathcal{L}(T''_n) \xrightarrow{\text{wa}} \mathcal{L}(T'_{n}), \quad n \to \infty,$$

if and only if for each $t \in \mathbb{R}^1$

$$f_n(t) - g_n(t) \to 0, \quad n \to \infty.$$

**Proposition 8.** (The Continuity theorem for weakly approaching random d.l.s). Let $\{\mathcal{L}(T'_n | X'_n)\}_{n \geq 1}$ and $\{\mathcal{L}(T''_n)\}_{n \geq 1}$ be two sequences of d.l.s and $\{\mathcal{L}(T''_n)\}_{n \geq 1}$ be tight. Then

$$\mathcal{L}(T'_n | X'_n) \xrightarrow{\text{wa}(P)} \mathcal{L}(T''_n), \quad n \to \infty,$$

if and only if for every $t \in \mathbb{R}^1$

$$f_n(t | X'_n) - g_n(t) \xrightarrow{P} 0, \quad n \to \infty.$$

**Proof.** See Theorems 1 and 2 in Belyaev and Sjöstedt-de Luna (2000).

**Proposition 9.** (The Stability Theorem for weakly approaching d.l.s). Let $\{T'_n, U_n\}$ be a sequence of pairs of r.v.s defined on the same probability space as $X'_n$ and let $U_n \xrightarrow{P} 0, \ n \to \infty$. If $\{T''_n\}_{n \geq 1}$ is a tight sequence of r.v.s and $\mathcal{L}(T'_n) \xrightarrow{\text{wa}} \mathcal{L}(T''_n)$ ( $\mathcal{L}(T'_n | X'_n) \xrightarrow{\text{wa}(P)} \mathcal{L}(T''_n)$), $n \to \infty$, then also

$$\mathcal{L}(T'_n + U_n) \xrightarrow{\text{wa}} \mathcal{L}(T''_n), \quad \mathcal{L}(T'_n + U_n | X'_n) \xrightarrow{\text{wa}(P)} \mathcal{L}(T''_n) \quad \text{as} \quad n \to \infty.$$  

**Proof.** See Lemmas 7 and 8 in Belyaev and Sjöstedt-de Luna (2000).

**Proposition 10.** Let $\{T''_n\}_{n \geq 1}$ be a sequence of real-valued r.v.s defined on the same probability space as $X'_n$, $\{T'_n\}_{n \geq 1}$ be a tight sequence of r.v.s and
Let \( \mathcal{L}(T'_n \mid X'_n) \xrightarrow{w^p} \mathcal{L}(T''_n), \ n \to \infty \). Suppose that the sequence of distribution functions (d.f.s) \{G_n(\cdot)\}_{n \geq 1} of r.v.s \( T'_n \) is uniformly continuous. Then

\[
\sup_{z \in \mathbb{R}} | F_n(z \mid X'_n) - G_n(x) | \xrightarrow{P} 0 \quad \text{as} \quad n \to \infty,
\]

where \( F_n(\cdot \mid X'_n) \) is the conditional d.f. of \( T'_n \) given \( X'_n \).

**Proof.** See Lemma 9 and Corollary 1 in Belyaev and Sjöstedt-de Luna (2000).
