The Krycklan Catchment Study

A unique infrastructure for field based research on hydrology, ecology and biogeochemistry

A Hitcher’s Guide 4.0

Hjalmar Laudon
2019
The 68 km² Krycklan catchment encompasses the natural mosaic of boreal landscapes consisting of forests, mires, streams and lakes that make up 70% of the area in Sweden, and which is representative of 30% of the world’s forest cover.

Krycklan is an integral part of the Svartberget field research infrastructure, which belongs to the Swedish University of Agricultural Sciences (SLU). The Svartberget field station is also responsible for Degerö stormyr, Rosinedal, Flakaliden and Norrliden.

The ongoing field activities include over 50 research projects, involving several hundred scientists from all major universities in Sweden and 30 countries. In total ~ 50 PhD students conduct research at the site. Over 1000 scientific publication are based on results from Svartberget since the beginning in 1910. There is also 110 PhD-thesis (the first published in 1923) where approximately half are based directly on the Krycklan catchment.
Location of the Krycklan catchment and other related study areas. The smaller dots are part of the national forest production research network consisting of 1400 sites across Sweden.

SITES is a national coordinated infrastructure for terrestrial and limnological field research. SITES consists of nine research stations, including Svartberget/Krycklan. The stations are distributed all over Sweden covering the different landscapes and climatic regions, including agricultural land, forests, mountains areas, wetlands, several type of inland waters, boreal catchments, tundra ecosystems etc.

SITES is available for all researchers on equal terms, regardless of affiliation. SITES offers facilities, sampling equipment and use of data generated from installations and/or observations in the field.

The SITES initiative is funded by the Swedish Research Council and the five partner organisations, i.e. the University of Gothenburg, the Swedish Polar Research Institute, Stockholm University, Uppsala University and Swedish University of Agricultural Sciences. The latter also hosts and coordinator SITES.

Much of the structures described in this guide can also be found on other SITES stations as part of the SITES Water programme. Read more at www.fieldsites.se

Left: Location of research stations within SITES
SITES AquaNet

This is a standardized infrastructure for national and international researches to run mesocosm experiments in lakes at Asa, Erken, Skogaryd, Svarthberget and Bolmen field stations.

Mesocosm enclosures: Each site is equipped with a jetfloat deployed in stortjan with 20 polyethylene cylindrical enclosures for experimental manipulations.

Sensor measurements: The experimental facilities have a sensor and datalogging system to measure in each mesocosm real-time environmental parameters.

Standardized sample collection and analyses: Each station is equipped with field equipment for sample collection and access to cold storage, freezing rooms and laboratory facilities. There is connection to laboratories for further sample analyses at the SLU.

Research topics: biodiversity-functioning-stability relationships, community ecology, ecological stoichiometry, food web interactions, benthic-pelagic dynamics, biogeochemistry (e.g., nutrient cycling), land-water-air gas exchange, cyanobacterial blooms and global change research.
ICOS – Integrated Carbon Observatory System

ICOS is a European research infrastructure for quantifying and understanding the greenhouse gas balance of the European continent and of adjacent regions. ICOS collaborates with nationally operated measurement stations in 17 European countries. ICOS Sweden (http://www.icos-sweden.se) consist of three atmospheric, six ecosystems and one ocean station.

ICOS in Vindeln combines atmospheric and forest ecosystem site at Svartberget and one mire ecosystem site at Degerö stormyr.

At Svartberget, the tower is 150m high where CO₂, H₂O, air temperature, incoming and outgoing radiation, soil moisture, soil heat flux, temperature, canopy radiation and tree temperature are measured. www.icos-sweden.se
Half of the precipitation in Krycklan leaves as evapotranspiration (ET). ET is not a uniform flux but consists of two fundamentally different pathways:

**Evaporation** (E) from wet surfaces

**Transpiration** (T) through stomata of plants

These pathways of water loss are controlled by environmental factors and thus are likely to respond differently to climate change. In 2016, we started using a combination of techniques (sap flow sensors, eddy covariance, stable isotope measurements) to better understand the processes, patterns and mechanisms controlling the movement of water.

Left: Preliminary data of the isotopic signature of xylem water ($\delta^{18}O$) in Scots pine (green) and Norway spruce (red) during the growing season. Event based precipitation are blue diamonds and stream discharge are light blue stars.

Right: ET as measured by the eddy covariance technique (light blue) and tree transpiration measured using sap flow sensors (dark blue). Tree transpiration accounted for ca. 45% of total ET.
A Field Guide of the Krycklan Catchment

Trollberget Research Infrastructure

Millions of hectares of northern peatlands were drained for forestry which has increased forest productivity in some areas, but not all. The future fate of these drainage ditches can be to:

1) clean them to ensure continued drainage,
2) ecologically restore them to a more natural state, or
3) leave them alone.

In fall of 2018, we added eight stations to the Krycklan water quality monitoring network in a side-by-side comparison of these three different management options with the goal of determining their effects on water quality and quantity.

We call this area “Trollberget” and it began with the EU LIFE program’s GRIP on LIFE Integrated Project that includes demonstration areas for the restoration of an unproductive drained peatland and best practices for cleaning of forest ditches.

Above left: Stormyr is an unsuccessfully drained mire that will be restored.

Above right: Old drainage ditches within a >100 year old spruce forest will be cleaned with best practice methods after the forest is harvested.
Above: Map of the proposed treatments & research infrastructure of Trollberget. The sampling points are weirs were water flow and quality are measured as of 2018. We will construct Eddy Covariance Towers in the future. Management actions will be done in 2020.

The original project has expanded to include other studies of forestry practices, including forest harvest, site preparation, and riparian buffer design as well as other potential environmental effects from these management actions, including greenhouse gas emissions, carbon and water cycling, and biodiversity, among others.

Participants and funders:
Above: The Svartberget catchment (C7) is the centre of Krycklan.

The catchment with many names (Svartberget, Nyänget, SVW, C7) is where it all began in 1979. It is also the heart of much of the current research on the contrasting hydrological and biogeochemical behavior of forested and mire catchments in Krycklan. The Svartberget catchment also hosts the first soil experimental and monitoring sites that begun in 1997, including the S-transect and the “Russian wells”.

The Svartberget Catchment
A Field Guide of the Krycklan Catchment

Left: Decline of pH during the spring flood at C7. This decline is mainly driven by natural processes caused by increases in the concentration of DOC (Dissolved Organic Carbon).

Below: The contrasting behavior of DOC between the forested catchments and wetland dominated catchments.

Forest Catchment (C2)  Wetland Catchment (C4)

Key references

Regions in red indicate the sensitivity of the soil C stocks. In a global perspective northern boreal soils are among the most sensitive in the near future to climate warming because soils with large carbon stocks are not permanently frozen, and rapid increases in temperature are already observed.

Key reference
Northern freshwaters are changing rapidly in response to global warming and human perturbation. Despite this there is an ongoing downsizing of small research catchments in the north. This is problematic as such research infrastructures are needed to understand and predict sustainable ecosystem services and social prosperity in this rapidly changing region.

In C7 discharge has been measured since 1980 (above right), C2 and C4 from 1994 and the remaining stations from 2004. There are 18 regularly monitored water quality monitoring stations (above left). Six of the stations are in heated houses for year around measurements (left).

Below: Discharge in the different sub-catchments as determined by different catchment characteristics (Karlsen et al. 2016).
Above: Simulated future streamflow in 14 sub-catchments. The reference period (blue) and future (orange) climate conditions are shown. The dark curve presents the median of all simulations (Teutschbein et al. 2016).

**Key references**

Above: Krycklan and the stream carbon monitoring program. The grab sampling program begun 2002 and includes ~30 samples of DOC, CO₂, CH₄ and UV spec per year. The sensor network is continuously being expanded but focus on the central parts of the catchment.

Left: Annual export of DOC from the different sub-catchments in Krycklan. Note that the export of DIC can be as large, or even larger. Here you can also see how the streams are connected.
Above: Grouping of common optical DOC indexes by land cover (Kothawala et al. 2015).

**Key references**

The contrasting behavior of different elements in the landscape depends on 1) its affinity to organic matter and 2) the primary source of the element. For the examples above, thorium (Th) and lead (Pb) affinity to organic matter are similar but Th is a weathering product while Pb originates mainly from deposition. Similarly, another relationship can be seen with pH which increases as the catchment size increase.
Increasing catchment size

Above: Iron speciation changes from the upstream low pH streams to the downstream increase in pH (Neubauer et al. 2013).

Key references

The riparian zone has a disproportional large impact on the stream biogeochemistry. Partly this is because it is the large last environment the soil water meets before becoming surface water. But this large influence also has to do with the fact that the riparian soil in the boreal region is highly organic rich, and therefore very different compared to most other soils in the catchment. The S-transect was installed 1997 and has been sampled monthly since.

The transect consists of ceramic suction lysimeters at 5-7 depths in three plots (below): in the riparian zone 4 m from the stream (S04), 12 m from the stream (S12) and in the upslope mineral soil 22 m from the stream (S22).

The installations are made so that samples can be collected all year by using a heating cable where the water passes through the frozen soil. The hydrology (above) is focused in the upper horizons due to the hydrological conductivity which increases exponentially towards the soil surface.
A Field Guide of the Krycklan Catchment

Right: Pattern of DOC in the S-transect. Note the very high concentration in the riparian zone and the much lower concentration uphill.

Above: Contrasting patterns of strontium, which has low affinity to DOC and aluminium, which has a very high affinity to DOC. Most other elements in the periodic table behave similarly depending on their DOC affinity.

Key references

The soil frost experiment started in 2002 which makes it the longest ongoing experiment of its kind in the world. Winter conditions in the soil are strongly dependent on the timing and amount of snow. Little snow gives very cold soils, whereas early and large amounts of snow will result in “warm” soils.

Colder soils and deeper soil frost gives higher DOC concentrations in the upper soil layers

Colder soils also gives rise to higher DOC concentration in the streams during the spring flood. (From Haei et al. 2010).
Left: The DOC quality is affected negatively by the length of winter. Here it is measured as SUVA. (From Haei et al. 2011).

Below: CO₂ concentrations at different depths in the soil over two years without soil frost (left) and with extensive soil frost (right). (From Öquist and Laudon, 2008)

Key references

The riparian observatory is distributed at 20 locations in Krycklan and is designed to investigate the soil-surface water interaction in terms of hydrology and biogeochemistry. It is similar to the S-transect in design at 7 locations with transects from uphill to riparian zone.

Each of the RO sites has installations for soil water, soil gas sampling and ground-water (GW) monitoring. Seven of the sites have installations both in the riparian zone and uphill, 20-30 m away from the RO site to study the chemical evolution of water along the flow pathway.
The TOC concentration (mean weighted) is well correlated with the average groundwater table in each location (left), with the exception of RO14 which is located on sediment soils. The average groundwater table (right) is in turn strongly correlated with the TWI (topographic wetness index). As TWI can be calculated using topographic maps this is a way forward to predict TOC in the riparian soils (From Grabs et al. 2012).

**Key references**

The Kallkäls mire is the source area for stream C4, and the location of the “Russians wells”. The “Russian wells” are a set of piezometers allowing sampling at different depth in, and below the mire.

Left: Flow pathways through the mire during spring, summer and autumn using stable isotope oxygen -18 (δ¹⁸O) as tracers. Note the two dominating pathways, 1. As overland flow and 2. Through the mire at 200 to 300 cm depth at some preferential pathway (From Peralta-Tapia et al. 2015).
Profile of chemical analyses following the pathway of water as it flows from the mineral soil into the mire. Here we show the activity (concentration) of thorium (Th) (above a) which is an element with a high affinity to DOC and radium (Ra) (below b) with low affinity to DOC (From Lidman et al. 2012).

Key references

Above: Groundwater wells in Krycklan.

In total, close to 20 wells are installed spanning from 5 m to over 150 m depth. The installations were made to cover the entire catchment to investigate regional groundwater as well as allow more local studies of water pathways. The first wells were installed by the Swedish Geological Survey (SGU) in the 1980s and have been monitored since, whereas the majority was installed in 2012.

Left: Schematic figure of water flow pathway in Krycklan (Peralta-Tapia et al. 2015) showing the long travel distance for water surfacing downstream in the larger rivers.
The profile view shows the 150 m ICOS tower and major groundwater wells ranging between 5 and 153m.

Krycklan is supported by a state of the art Lab that is equipped with standard instruments for analyzing approximately 2500 samples per year in soil and water chemistry following standard operating procedures.

Some of the facilities available includes:

**Storage**– Cool room  
  Dry room  
  Freezers for long-term storage

**Analysis**–
  Isotopes and Gas Analyser  
  Titrator-pH and conductivity  
  Aqualog-florescence and absorbance  
  Shimadzu TOC-VPCH analyzer  
  Gas Chromatography  
  Fume Hoods  
  MQ water

**Database**– An active database that updates current analysis onto the [Svarberget data-portal](https://franklin.vfp.slu.se/) for easy data sharing possibilities and long-term storage possibilities.

Data includes:
Stream Chemistry,  
Climate,  
Flux measurements,  
Hydrological Loggers,  
Groundwater chemistry,  
Precipitation Chemistry
Research in Krycklan started over 100 years ago with the study of paludification effects on forest growth. In the 1970’s, the Svartberget field station was established. Research then was focused more on forest hydrology and biogeochemical cycling. During the 1990’s, a decade of more intensive work on the role of acid deposition on stream water chemistry contributed to new views of anthropogenic acidification and natural acidity in organic carbon-rich boreal waters. In recent years, the research scope expanded substantially to include more work on biogeochemistry, carbon cycling, hydrology and ecology. More intensive research also began on the connections between soils and surface waters, leading to a process-based understanding of the regulation of stream water chemistry.

Recognition of the need to work at the landscape scale when addressing climatic influences on aquatic ecology led to the expansion of the Svartberget catchment from 50 ha to the 6800 ha Krycklan catchment in 2002. This has further increased the research scope to include both fundamental research questions as well as management issues that are currently addressed.

In recent years, Krycklan has transformed into a unique experimental platform for testing pure and applied research questions in a natural environment. The platform continuously attracts new scientific projects as well as directly collaborates with the Swedish Nuclear Waste Program, Swedish EPA, Sveaskog and others.

Krycklan would not be possible without the excellent support from the field and laboratory crew.
